International conference on fast ionic transport in solids, Gatlinburg, TN, USA, 18 May 1981.

It is shown that the Nernst-Einstein equation can be generalized for a high defect concentration solid to relate the mobility or conductivity to the self-diffusion coefficient. This relationship is derived assuming that the diffusing particles interact strongly and that the mobility is concentration-dependent. It is derived for interstitial disordered structures, but it is perfectly general to any mechanism of self diffusion as long as diffusion in a pure system is considered. (ERA citation 06:024516)

The importance of polarization effects due to the diffuse nature of the wavefunctions in the relaxed excited states are emphasized, and the usefulness of an effective mass approximation indicated. Several approaches to the calculation of the electronic structure are discussed and evaluated. The connection between electronic structure calculations and phonon perturbations are pointed out through a brief discussion of localized perturbation theory. (ERA citation 06:024517)

The effect of a variety of plasma cleaning procedures on the level of bulk and interfacial contaminants in the films is analyzed by secondary ion mass spectrometry. Bulk levels of 0 have been reduced considerably by N sub 2 plasma cleaning, but no reproducible reductions in interfacial contamination have been achieved. A method is described of determining the gap state density

N(epsilon) of a-Si:H from field effect, in which no assumptions are made about the form of the band bending in the semiconductor. The problem is reduced to three successive integrals over an assumed N(epsilon) by change of variable from distance to applied voltage and the best fit to the experimental data is obtained by iteration of the assumed state density. The method is shown to be no less rigorous and considerably more economical than the recent analysis of Goodman, Fritzsche and Ozaki. In addition, an experimental means of determining the flat-band voltage to within 5% of the maximum gate voltage V/sub g/ used is demonstrated, by finding the value of V/sub g/ for which (kT/e)dlog I/sub SD//dV/sub g/ is independent of temperature. The first objective is to determine whether field effect could be observed in samples of sputtered hydrogenated amorphous silicon, and, if it could, to compare the pseudogap density of states determined therefrom with estimates made by other methods of investigation. The second is to determine the drift mobility of excess carriers in these materials by time-of-flight, and to interpret its magnitude and temperature dependence in terms of current theories of transport in disordered semiconductors. The field effect has been observed, but the conditions required are such as to imply that deductions of the state density from it may not accurately represent the bulk density of states. In the course of this work a simpler method of reducing field effect data has been developed. The drift mobility has also been measured, but these experiments have not yet assembled sufficient statistics for final conclusions to be drawn from them. (ERA citation 06:022311)

A process is given for producing a variety of organic-inorganic luminescent and semiconductive compounds or materials in the form of a film deposited directly on the surface of a substrate by ultraviolet photoinduced condensation from gaseous reactants such as antimony pentafluoride (SbF5)n and organic or inorganic halogen-containing compounds. The process provides a new class of antimony (Sb) doped luminescent and semiconductive materials which can be produced on any arbitrary size or shape substrate, or even on existing substrates of other semiconductive materials or chips, to form semiconductive devices. The process may be used in photoinducing luminescent panel displays or microelectronic circuits, such as integrated electrical or optical circuits. (Author)

Temperature dependence of electrical conductivity was analyzed for three sublimation-grown crystals, three iodine transport crystals, and three polycrystalline samples, using measured Hall effect mobility data on some samples and a multi-impurity computer model. In sublimination-grown single crystal and polycrystalline samples three levels dominate: less than or equal to 0.02 eV, 0.25 eV, and 0.47 eV. Relatively good fits can be obtained to measured data with simple computer models involving two or three acceptors and one donor. A literature search has been done on the optical properties of Zn sub 3 P sub 2 , resulting in a composite absorption vs photon energy curve. Evidence for split valence bands is obtained from ac photoconductivity measurements, and initial exploratory measurements have been made on laser-excited photoluminescence at 2 to 15 exp 0 K. A detailed investigation was made of the commonly found non-stoichiometry of the Zn sub 3 P sub 2 films deposited by CSVT (usually about 25% excess Zn), and considerable evidence amassed to indicate that the excess Zn is localized near the surface of the film and in voids in the film. Investigation of the Numerical Methods of Finite Differences and Weighted Residuals for Solution of the Heat Equation.
Master's thesis,
Robert Earl Naegeli. Mar 82, 99p Rept no. AFIT/GNE/PH/81-7

The method of weighted residuals applied on the whole domain for steady state and transient heat generation problems was compared to finite difference methods. The comparison consisted of the maximum absolute error from the exact solution and computer time required for solution. One steady state and one transient heat generation problem were solved by collocation and Galerkin weighted residual methods and finite differences. The least squares weighted residual method was also used for the steady state problem. Both problems were one-dimensional and had Dirichlet boundary conditions. Integrals for weighted residual methods were evaluated analytically to produce recursion relations. The transient problem was solved by the reduction to ordinary differential equations method for weighted residuals. The Galerkin method was fastest to a given accuracy for both problems evaluated. The accuracy of Galerkin and other weighted residual methods was greater than finite differences after a point at low solution accuracy. This crossover point was typically two to three digits of accuracy. The polynomial trial functions used for weighted residual solutions exhibited a numerical instability for solutions of 10 terms and over increasing the maximum absolute error. Orthogonal collocation and weighted residuals on finite elements were recommended as alternate methods. (Auhtor)

Measurements were made of the spin-lattice nuclear relaxation time of 0.07% solutions of polarized helium-3 in liquid helium-4 at 4 K by use of an rf-biased SQUID (Superconducting Quantum Interference Device) magnetometer in magnetic fields ranging between 30 microGauss and 3 milliGauss. After the effect of magnetic-gradient-induced relaxation was subtracted by extrapolation to large magnetic fields, it was found that the relaxation time was 40 hours in a 1 cm-diameter pyrex cell. When the sample cell was prefilled with an amount of hydrogen estimated to be equivalent to uniform wall coating of 30 molecular layers thickness, the extrapolated relaxation time increased to 5 days. It is estimated that this result was dominated by intrinsic relaxation due to helium-3 dipole-dipole interactions in the bulk of the sample. As a potential application, the performance of a proposed cryogenic nuclear gyroscope utilizing a helium-4 -- polarized helium-3 gas mixture with SQUID magnetometer readout in zero magnetic field is theoretically analyzed. The possibility of using a modified version of this device based on a polarized helium-3 -- superfluid helium-4 mixture for the purpose of an experimental search for an electric-dipole moment in the helium-3 nucleus is also discussed. An airborne man-made radio noise model has been developed and programmed on a graphics computer at the Naval Ocean Systems Center. This model provides a useful approximation to the geographical dependence of airborne man-made radio noise in the continental United States. Radio noise maps produced from this model are used to evaluate the effect of man-made radio noise on the operation of meteor burst communication systems. Equations developed by Skomal (E. N. Skomal, Man-Made Radio Noise, Van Nostrand Reinhold Co., New York, 1978) are used to construct the model. Two parametric equations are used to model the height gain of man-made radio noise as a function of distance, 0 to 150 miles, from the source. Coefficients for these equations are calculated from data measured over Seattle (W. E. Buehler and C. D. Lunden, IEEE Trans. Electromagnetic Compatibility, EMC-8, 143-152, 1966). Two hundred of the nation's largest cities and 62 of the largest counties and military installations are used as sources of radio noise in the computer program. Day and nighttime contours can be produced in the 25 to 75 MHz range for altitudes between 30 and 70 thousand feet. (Author)

Simple analytic approximate expressions have been derived for ELF propagation constants in the earth-ionosphere waveguide. The expressions are

an extension of previous work to a more general class of ionospheric-conductivity height profiles. The expressions derived here allow the rapid computation of ELF phase speeds, attenuation rates, and excitation factors for a wide range of ionosphere conditions without the necessity of lengthy full-wave computer calculations. The results can be applied to the rapid evaluation of the effects of a variety of ionospheric disturbances, both natural and artificial, on ELF communication systems. (Author)

VLF transmission experiments were conducted from sites in North Norway during selected time periods in 1978, 1979 and 1980. Data from these experiments were collected from VLF receivers aboard the SCATHA (P78-2) and GEOS satellites and VLF receivers on the ground at various locations in Norway and Sweden. Direct signals were measured at each of the ground stations and emissions triggered by the transmissions were detected by the satellite receivers. This report documents the impedance measurements made on each of three power lines used as VLF antennas and summarizes the preliminary results from the VLF receiver data. (Author)

Coherent anti-Stokes spectroscopy (CARS) can be considerably simpler than is suggested by literature analyses based on interactions of monochromatic waves. The simplification arises when the optical properties of real lasers are incorporated into the analysis. To incorporate these properties, it is necessary to recognize that the underlying nonlinear optical interaction has a previously ignored complexity and is dependent on the coherence properties of the fields as well as on their spectra. The coherence of the interaction, as described by the CARS linewidth parameter, is degraded by the imperfect coherence of the laser sources. The occurrence of the nonlinear interaction depends on the small size of laser mode widths, or more fundamentally, on the statistical degeneration of each incident field into a small number of independent fields, a property possessed only by optical fields from lasers. If the lasers' contributions to the linewidth parameter are made dominant, the degree of coherence becomes a fixed property of the apparatus, simplifying interpretation of CARS spectra and extending the range of usefulness of CARS well beyond what would otherwise be expected. Available numerical values plus considerations of effects such as mode frequency chirp suggest that domination of the coherence by the apparatus can be arranged or at least approached in most cases.

The study of the oxidation kinetics of pyridine was completed in the temperature range of 948 to 1073 exp 0 K and concentration ranges of 1.75 to 7.0 mole % oxygen; 0.25 to 2.0 mole % pyridine. The rate law is rate = k(C sub 5 H sub 5 N)/sup 1/2/(0 sub 2)(delta 0 sub 2)/sup 1/2/, where delta 0 sub 2 is oxygen consumed (autocatalysis). The temperature dependence is k = 10/sup 14.7 +- .7/ exp(-26600 +- 1600/T)(1/mole s). The yield of HCN appeared insensitive to changes in temperature, concentrations and equivalence ratio, and only trace amounts of nitrogen oxides and ammonia were found. Fuel-rich mixtures produced large amounts of smoke so that a nitrogen balance was not possible but for lean mixtures HCN and N sub 2 accounted for the product nitrogen. Increase to 2% pyridine and 14% oxygen produced reduced yields of HCN and increased yields of N sub 2 , N sub 2 O, and NO. H sub 2 had no influence on the rates of pyrolysis and oxidation of pyridine. At 1073 exp 0 K HCN was oxidized at a measurable rate, added benzene increased the rate of oxidation at low equivalence ratios and reduced it at ratios above 0.9, with no significant nitrogen oxides produced, added acetylene increased the oxidation rate and also produced NO. It is clear that conditions can be found for the oxidation of heterocyclic nitrogen compounds that promote the formation of N sub 2 at the expense of NO. (ERA citation 06:022414)

Evolution of Fuel Nitrogen During the Vacuum Thermal Devolatilization of Coal.
J. D. Freihaut, and D. J. Seery. 1981, 18p
Contract AC21-78ET10744

The fate of fuel nitrogen during the combustion or gasification of coal is a matter of practical and fundamental concern. During coal combustion, NO/sub x/ is known to form via HCN species released from the nitrogen-containing molecular components of the coal. During gasification processes, the release of nitrogen-containing fused ring compounds in evolved tar species is a matter of environmental concern. Since the thermal decomposition of the parent coal is an initial phase in both combustion and gasification, it is necessary to develop a knowledge of the fate of fuel nitrogen during thermal decomposition. This study contains results of an investigation of the evolution of fuel nitrogen during the vacuum thermal decomposition of coal. Results are shown for variations with coal characteristics and apparent thermal history. Apparent heating rates of 75 C/sec to 2000 C/sec and final temperatures of 500 C to 1780 C were utilized. A variety of coals were investigated ranging in rank from lignite to anthracite. The results indicate that nitrogen distribution in the volatiles is a sensitive function of the chemical characteristics of the parent coal. This distribution of nitrogen in the light gas, tar and char products of vacuum devolatilized coal is highly dependent on rank of the parent coal. Variations in nitrogen evolution with coal characteristics are most readily apparent in several aspects: (1) the coal nitrogen released with the tar species; (2) the release of nitrogen contained in primary tars as HCN upon secondary thermal decomposition reactions of the primary tars; (3) the retention of nitrogen in the char species. Contract AC22-77ET11287

Over the past three and one half years, substantial research efforts of the Princeton Fuels Research Group have been directed towards the development of simplified mechanisms which would accurately describe the oxidation of hydrocarbons fuels. The objectives of this combustion research included the study of semi-empirical modeling (that is an overall description) of the chemical kinetic mechanisms of simple hydrocarbon fuels. Such fuels include the alkanes: ethane, propane, butane, hexane and octane as well as the critically important alkenes: ethene, propene and butene. As an extension to this work, the study of the detailed radical species characteristics of combustion systems was initiated as another major aspect of the program, with emphasis on the role of the

OH and HO sub 2 radicals. Finally, the studies of important alternative fuel problems linked the program to longer range approaches to the energy supply question. Studies of alternative fuels composed the major elements of this area of the program. The efforts on methanol research were completed, and while the aromatics aspects of the DOE work have been a direct extension of efforts supported by the Air Force Office of Scientific Research, they represented a significant part of the overall research effort. The emphasis in the proposed program is to provide further fundamental understanding of the oxidation of hydrocarbon fuels which will be useful in guiding engineering approaches. Although the scope of program ranges from the fundamentals of chemical kinetics to that of alternative fuel combustion, the objective in mind is to provide insight and guidance to the understanding of practical combustion environments. The key to our approach has been our understanding of the fundamental combustion chemistry and its relation to the important practical combustion problems which exist in implementing energy efficient, alternate fuels technologies. Most of the effort was devoted to the model element improvement in four areas: Chemical reactions of OH and O radicals with carbon surfaces; effect of particle size distribution on optical absorption properties of the coal feed; dynamics of a distribution of particle sizes; and development of scaling laws for the location and shape of recirculation zone boundaries. The conclusions from these efforts are: 1) the chemical reactions of OH and O radicals with carbon surfaces are very rapid at combustion temperature. The reactions are first order in total pressure and yield CO as the primary product. Optical absorption coefficients of Rosin-Rammler distributions of typical pulverized fuel are about three times the value for mass mean particle size. The model will include the optical absorption coefficient appropriate for the size distribution within the combustor. The particle size distribution has a significant effect on the particle velocity distribution and thus on residence times of the larger particles. Calculations of particle dynamics are underway. An exhaust search was conducted for literature related to flow patterns in axisymmetric, confined, combusting flows, both with and without swirl. Correlation of various experimental results was attempted. (ERA citation 06:023078)

P. J. Smith, and L. D. Smoot. Oct 79, 227p

A one-dimensional, steady-state model describing pulverized coal combustion and gasification is presented. While emphasis has been placed on the description of the coal reaction processes and gas-particle interactions, one-dimensional fluid mechanics and particle-particle, particle-wall radiation have been included. Moisture vaporization from the coal particles, multi-step coal pyrolysis, and heterogeneous char oxidation by multiple oxidizers are modeled for polydispersed coal particle sizes or types. Although the formulation is one-dimensional, mixing rates of primary and secondary streams and recirculation within the reactor have been accounted for as specified input. The resulting model predicts thermal, chemical and physical histories for both the gaseous and particle phases. Gas-particle interactions account for appropriate diffusion and kinetic rates. Gas phase reactions are assumed to be in local chemical equilibrium. The solution technique uses predictor-corrector methods for integration of the ordinary non-linear differential equations which are coupled with a number of auxiliary algebraic equations. An iterative approach is required for the radiant heat transfer calculations by the zone method. Stiffness in differential energy equations is overcome by a pseudo steady-state method when needed. The generalized nature of the model allows for calculation of both coal combustion and coal gasification characteristics. User information is presented, along with a sample computation and a listing of the program. (ERA citation 05:021724)

Some advances in component technology for inert gas thrusters are described. The maximum electron emission of a hollow cathode with Ar was increased 60-70% by the use of an enclosed keeper configuration. Operation with Ar, but without emissive oxide, was also obtained. A 30 cm thruster operated with Ar at moderate discharge voltages give double-ion measurements consistent with a double ion correlation developed previously using 15 cm thruster data. An attempt was made to reduce discharge losses by biasing anodes positive of the discharge plasma. The reason this attempt was unsuccessful is not yet clear. The performance of a single-grid ion-optics configuration was evaluated. The ion impingement on the single grid accelerator was found to approach the value expected from the projected blockage when the sheath thickness next to the accelerator was 2-3 times the aperture diameter.

This program examines the applicability of a proprietary blending process to blending antimisting additives in JET A aviation fuel. The first phase of the program covers use of the process with a high molecular weight polyisobutylene. The second phase covers the use of the process with Imperial Chemical Industries, Ltd's proprietary polymer, FM-9. The results of the program indicate that high molecular weight polyisobutylene can be blended rapidly with JET A using the proprietary process and that the resulting blend demonstrates antimisting behavior within minutes. There was no evidence that the proprietary process is effective in the blending of FM-9 in JET A. (Author)

Shale-derived JP-5, JP-8, aviation turbine fuels and marine diesel fuel were analyzed for compliance with military specifications and evaluated for storage stability, corrosion tendencies, additive response, compatibility with petroleum fuels and microbiological growth susceptibility. The shale fuels behaved very much like petroleum-derived fuels. Turbine combustor evaluation showed a likeness to petroleum-derived Jet A fuel. Performance tests of the shale fuels conducted in four diesel engines also indicated a similarity with the same tests performed with petroleum-derived fuels. (Author)

Hydrogen Production by Fluid-Bed Retorting of Oil Shale.

Contract W-7405-ENG-36
Microfiche only after original copies are exhausted.

The oil produced from retorting of oil shales requires hydrogen treatment to improve its characteristics and make it suitable for refining into marketable products. Hydrogen requirements can be met by partial oxidation of a fraction of the shale oil produced or by direct processing of oil shale in a fluid bed. This report examines the economics and engineering feasibility of using fluid bed systems to produce hydrogen. Fluid bed processing of oil shale to produce hydrogen might be technically and economically competitive with a more conventional shale retorting/partial oxidation method. A major development program would be required to demonstrate the feasibility of the fluid bed approach. (ERA citation 06:023241)

A technical and economic feasibility study of a partial oxidation unit (Union Carbide Corporation's PUROX system) was conducted. Major objectives of the program were: (1) disposal of both urban (municipal refuse and sewage sludge) and agricultural (dairy) wastes, and (2) the production of a medium-Btu fuel gas. The investigated wasteshed includes those portions of Western San Bernardino County, Eastern Los Angeles County, and Northwestern Riverside County. Section 2 is a summary chapter. The available waste supply (municipal refuse, sewage sludge, dairy wastes) is discussed in Section 3. Transportation of these waste materials is discussed in Section 4. Product quantities and energy products of fuel gas, steam, and electricity are discussed in Section 5, Markets for Energy and Recovered Materials. Ferrous metals, aluminum, and nonferrous metals, and slag are the materials studied. (ERA citation 06:023774)

The dry milling process for the conversion of grain to fuel ethanol is reviewed for the application of energy conservation technology, which will reduce the energy consumption to 70,000 Btu per gallon, a reduction of 42% from a distilled spirits process. Specific energy conservation technology applications are outlined and guidelines for the owner/engineer for fuel ethanol plants to consider in the selection on the basis of energy conservation economics of processing steps and equipment are provided. The process was divided into 5 sections and the energy consumed in each step was determined based on 3 sets of conditions; a conventional distilled spirits process; a modern process incorporating commercially proven energy conservation; and a second generation process incorporating advanced conservation technologies which have not yet been proven. Steps discussed are mash preparation and cooking, fermentation, distillation, and distillers dried grains processing. The economics of cogeneration of electricity on fuel ethanol plants is also studied. (ERA citation 06:021732)

Distillate Price-Monitoring System. Final Report.

Contract FC01-78EI06278

In June 1977 the Main Office of Energy Resources, (OER), developed the Price Monitoring Survey, (PMS), to collect data to be analyzed and used as an indication of the average price of home heating fuels (Kerosene, No. 2) in the State and with less statistical validity at the county level. From a total population of approximately 500 fuel oil dealers a sample of 32 dealers was selected. The sample was selected from each of Maine's sixteen counties based on population centers with at least one sample point from each county. After sample selection was completed each of the 32 selected fuel oil dealers was telephoned and asked for the retail price of kerosene (number one), and the retail price of number two home heating fuel. In order to facilitate processing of survey results a computer program was developed. The program is interactive and is written in VSAPL. Each time the telephone survey is conducted input is verified and analysis is performed on the IBM-370 model 148 computer at the University of Maine at Orono. The OER believes that the program was a successful attempt to monitor price fluctuations in the home heating oil, retail market and intends to continue the program. It is felt that the program should be expanded to motor gasoline. Tables and graphs relating to the data collected are provided. These attachments depict price fluctuation over time and display the outputs of the program. (ERA citation 06:021583)

Program to Monitor the Weekly Retail Price of Home-Heating Fuel Oil No. 2 in the State of New Jersey. Year One Final Report.

Contract FC01-79EI10169

In order to enable the Energy Information Administration (EIA) of the United States Department of Energy (US DOE) to execute its role in monitoring the cost and price movements within the United States' petroleum industry and to perform analyses and projections related to energy supplies, demand, and prices, the US DOE and the New Jersey Department of Energy (NJ DOE) entered into a cooperative agreement effective between February 26, 1979 and May 30, 1979. The NJ DOE agreed to undertake a weekly program to monitor and evaluate price fluctuations of residential heating oil (No. 2) sold in the State of New Jersey. The sample was randomly selected from a list of home heating oil dealers for each county. Each of the heating oil dealers was advised by letter of the overall purpose of the survey and of the specific information which would be requested. The survey was conducted by telephone on each Monday for the period February 26, 1979 through May 30, 1979. The dealers were asked for the discounted price of home heating oil (No. 2) as of the close of business of the preceding Saturday. The discounted price was defined as the gross price less any discount for early cash payment (i.e., 2% discount for payment within 10 days). Overall state maximum, minimum, and mean prices were calculated as well as the mean for each county in New Jersey. These data were reported to the Region II EIA Data Coordinator by letter within one or two days of their compilation. The statewide maximum, minimum, and mean prices were also reported by telephone to the Washington office of the EIA. A table is presented in this report with these data. (ERA citation 06:021585)

Contract FC01-79EI10297

A one-time survey of the approximately 250 No. 2 fuel oil retail dealers in the state of Rhode Island was conducted by the Governor's Energy Office during July and August of 1979. The information that was sought included name of supplier(s), storage capacity, number of customers, historic deliveries and historic inventories. The total number of dealers who responded to each question ranged between 39 and 190. While the participation was somewhat limited, the survey nevertheless provided the Energy Office with its first profile of the state's retail No. 2 heating oil dealers. While the collection of historic data may be of interest, the collection of accurate and up-to-date data on the price and supply of No. 2 oil is absolutely vital to ensure that adequate supplies are available to the approximately 200,000 dependent Rhode Island households. Tables are provided giving the high, low and average prices of retail and wholesale prices of No. 2 heating oils and retailer margins, inventories, and deliveries. (ERA citation 06:021587)

Solar Photo-Catalytic Hydrogen: Systems Considerations, Economics, and Potential Markets. Final Report.

Contract AC03-80ER10190

A three part analysis was done consisting of (1) an examination of the physical principles of solar photocatalytic energy conversion and the status of research in this area, (2) an economic analysis of the potential costs of producing hydrogen from such a system, and (3) an analysis of the markets for hydrogen and the possible penetration of these markets by solar photocatalytic hydrogen. The cost range of flat plate thermal collectors, heliostats, and a photovoltaic system are compared. The cost range of flat plate thermal collectors was used to represent the cost of photocatalytic systems. On the basis of the photovoltaics cost outlook, it is found that photocatalytic systems would not cost less than $180 to $330 per m exp 2 range. On the basis of the heliostat cost outlook, a cost lower than $180 to $330 per m could be projected only for very large production volumes and very large installations. (ERA citation 06:023240)

Solvent-Refined Coal (SRC) Process. Vapor-Liquid Equilibrium Measurements for the SRC-II Process.

Contract AC05-76ET10104

This report summarizes vapor-liquid equilibrium studies conducted to support the Solvent Refined Coal project by the Pittsburg and Midway Coal Mining Company under contract with the Department of Energy. Discussed herein are experimental details and results of measurements to obtain vapor-liquid equilibrium data at conditions simulating those which occur during the gas-liquid separation steps in the SRC-II coal liquefaction process. Separation and compositional analyses of liquid and gas phases permitted calculation of the equilibrium K values for the various components of the mixture. Experimental methods and apparatus used in this work were compared to a system recently described in the literature. The measured K values agreed to within an average of +- 5% of published values and showed that the experimental system developed is satisfactory. Internal consistency of each experiment was evaluated by a material balance consistency test, and an average material balance of 99.7% was obtained over the 15 experiments. Data obtained from this work will serve as the basis for K value correlations used in process design calculations for the SRC-II Demonstration Plant. (ERA citation 06:023002)

The objective of the ESCOE Engineering Program is to provide independent assessments of key portions of energy RD and D programs conducted by the Department of Energy. These programs are aimed at development of technology that will permit rapid commercialization of processes or converting coal into products that substitute for those derived from oil and natural gas. The imposition of an embargo on recruitment of the professional staff and development of new technical tasks severely limits ESCOE's ability to continue planned and timely performance under the contract extension. The two principal professionals currently on board are scheduled to complete their residences between June and August. Similarly qualified personnel must be recruited now to ensure the selective, orderly and continued delivery of these technical services and knowledge to the Department of Energy. Development and Evaluation of Highly-Loaded Coal Slurries. Phase I Summary Report, October 15, 1977-December 31, 1978.
R. S. Scheffee. May 79, 202p
Contract AC22-77ET13041

Slurry fuels comprised of either bituminous, subbituminous, or lignite coal, and either aqeuous media or emulsions of No. 6 oil in water as the carrier were developed and evaluated at solids loadings up to 70% by weight. Emphasis was placed on aqueous slurries of bituminous coal. These slurries were developed for use in place of No. 6 oil in oil-fired burners. High solids loadings were attained by use of bimodal particle size distributions, which are blends of coarse-grind coal (approx. 50 to 85% -50 mesh) and fine-grind coal (generally 90% -200 mesh). The effect of the blends on slurry viscosity was determined to find the blends that minimize viscosity. The effect of mill conditions on particle size distribution was determined for each coal, using a hammermill pulverizer. A large number of water-soluble resins were evaluated for effect on slurry stability and viscosity. The best of these was found to be hydroxypropylated corn starch. Slurries based on the use of 3% solutions of the starch in water were prepared with up to 70% by weight bituminous coal and up to 65% subbituminous coal. The slurries are pourable pseudo-plastic fluids having room-temperature viscosities in the range of 550 to 1100 cp at a shear rate of 3000 sec exp -1 , depending on the type of coal, solids loading, and particle size distribution. None of the slurries exhibited hard pack settling, even after room-temperature storage up to 74 days. Oil-in-water emulsions made with polyethylene glycol (23) lauryl ether as an emulsifier were found to be stable with respect to phase separation when stored at 160 exp 0 F. Slurries made with these emulsions do not exhibit hard pack settling after one week storage at 160 exp 0 F. (ERA citation 06:023069)

Development and Evaluation of Highly-Loaded Coal Slurries.
E. T. McHale. May 80, 55p
Contract AC22-77ET13041

For the past two and one-half years Atlantic Research has been conducting a research program which involved development and combustion of slurries of coal in oil and in water. In Phase II good candidate slurries chosen from Phase I were burned in an experimental furnace and their combustion performance evaluated. Two slurry fuels were chosen for the combustion study. One consisted of a 50/40/10 (weight) coal/oil/water mixture, and the other was a 65/35 coal/water slurry stabilized with modified corn starch. The emphasis was placed on the coal/water slurry. Firings were conducted in a one MMBTUH experimental furnace constructed and instrumented for the purpose. A specially designed swirl burner/atomizer was developed for use with the coal/water slurry. Both slurries were burned successfully. Numerous firings were performed of up to one-half duration each. In the case of the coal/water slurry a small amount of gas assist was usually used, although this was eliminated in several shorter duration tests. Thermochemical calculations for coal/water slurries are presented. The presence of water in the slurry represents a relatively small energy penalty. A slurry made from a good coal will have a calorific value in the range of 10,000 Btu/lb. The heat required to vaporize the water of a 70/30 mixture is only about 300 Btu/lb slurry, or about 3 percent. Analysis of the results led to the conclusion that significant improvement in the burning maybe achievable, possibly to the point where combustion rates would be comparable to those of heavy oil. Because of the availability of coal, its cost advantage relative to oil, and especially because of the ease of handling of a liquid fuel, coal/water slurry appears to have considerable potential as a future fuel. Exploratory Study of Coal Conversion Chemistry. Quarterly Report, September 20, 1979-December 19, 1979.
5 Mar 80, 5p
Contract AC22-79ET14855

The objective of this task is to determine the mechanism of cleavage of key bond types in coal under nominal donor solvent coal conversion conditions. This is to be done by using selected model compounds as well as coals themselves under conditions comparable to those used in current donor solvent liquefaction processes. The specific model compounds have been chosen because i) they represent linkages and heteratom functionalities that are important in coals and ii) because their reported conversion rates are substantially greater than can be accounted for by the traditionally invoked free radical mechanism. Initially, we are focusing on a particular class of model compounds: hydroxylated diphenylmethanes. This class of compounds is important for two reasons: first, because the linkage and ring substituents are common in bituminous coals, and second, because it has been reported by Collins et al. that substitution of an -OH group on diphenylmethane makes the rate of conversion of hydroxy-diphenylmethanes to toluene and phenol (in Tetralin at 400 exp 0 C) roughly as fast as that of bibenzyl. The phenyl-CH sub 2 bond strength of hydroxyl diphenylmethane is at least 15 kcal/mole greater than the central bond in bibenzyl. Thus, if hydroxydiphenylmethane underwent conversion in tetralin by homolytic bond scission, its conversion at 400 exp 0 C would be slower by almost five orders of magnitude. In this report we discuss a possible mechanism that could account for this rapid conversion. Simple homolytic cleavage of the indicated bond in an intermediate would be fast, since it is at least 20 kcal/mole weaker than the central bond in bibenzyl. (ERA citation 06:023022)

Contract AC22-79ET14876

Run ZBF was conducted to determine the amount of sulfur and nitrogen removal from SRC-I/process solvent mixture in the absence of a hydrotreating catalyst. Negligible nitrogen and sulfur removal resulted from this experiment. The hydrogen content of the coal liquid increased slightly over that of the feedstock. In similar studies using other coal liquids some sulfur removal (10 to 40%) was noted under non-catalyzed conditions. Several commercial NiMo supported catalysts were analyzed for silica contents using atomic absorption. These results revealed that catalysts with large micropore size structures also contain high silica content (up to 22.5 weight percent). Several short duration runs (12 to 110 hours) were conducted in the CLTU to gather data on catalyst coking mechanisms. Using the SRC material mixed with a process solvent or creosote oil (30 weight percent SRC), solid materials were observed to form and precipitate in the latter portions of the reactor bed. The reactor system was modified to prevent the accumulation of these incompatible solids which would result in premature termination of the experimental runs. In the catalyst regeneration study (HDN-30, NiMo), a spent catalyst was regenerated and then used to hydrotreat a coal liquid consisting of 10% Synthoil II liquid mixed with raw anthracene oil. This regenerated catalyst gave equal and somewhat superior performance with respect to heteroatom removal compared to that of the fresh catalyst. A second regeneration of this same catalyst loading has been conducted and the regenerated catalyst is being prepared for a third cycle. The spent catalyst lost approximately 33% of its total surface area, yet regeneration recovered 97% of the fresh catalyst area. (ERA citation 06:023023)

Mechanisms and Kinetics of Coal Hydrogenation.

Contract AC22-79ET14881

Colorado School of Mines is engaged in an experimental program to develop comprehensive models for the effects of coal composition upon the kinetics and mechanisms of coal hydrogenation, for the effects of mineral matter additives (disposable catalysts) upon kinetics and mechanisms of coal hydrogenation, and for the kinetics and mechanisms of the hydrogenation of coal derived

products such as preasphaltenes, and asphaltenes. Experimental work was completed on a suite of bituminous coals, thus completing the initial phase of the coal reactivity study. Eleven of the 14 coals of the suite were successfully run in duplicate. Conversion to THF solubles was correlated well by pseudo-second order kinetics. The resulting kinetic rate constants correlated with H/C ratio, mean-max vitrinite reflectance, and a specially-defined fraction of reactive macerals. The data did not correlate well with O/C ratios of the parent coals. Computer-derived statistical fits of various kinetic models were limited in their effectiveness at fitting the experimental data. Experimental work on the first phase of the disposal catalyst studies was completed. Statistical significance testing of the experimental data showed: fractional conversion and yield of light hydrocarbon products increased with time; and mineral properties of the additives were more significant in increasing overall conversion than the additive surface areas. The relative effects of the additives are given. (ERA citation 06:023024)

Identification of Sulfur Heterocycles in Coal Liquids and Shale Oils. Technical Progress Report, August 1, 1980-May 1, 1981.

Contract AC02-79EV10237

The sulfur heterocycle separation scheme which was described in the last progress report was evaluated for quantitative recovery of individual components. The results indicate that recoveries can range from 10% to approx. 30% depending on the structure of the compound. During this period, 23 unsubstituted sulfur-containing heterocyclic ring systems were synthesized in oder to confirm GC/MS identifications and for biological testing. The four possible 3-ring heterocycles and the thirteen possible 4-ring heterocycles were tested for mutagenic activity in the histidine reversion (Ames assay) system. One of the 3-ring isomers, naphtho(1,2-b)-thiophene, and six of the 4-ring isomers induced mutations in Salmonella test strains. One of these compounds, phenanthro(3,4-b)thiophene, displayed approximately the same mutagenic activity as benzo(a)pyrene. A two-step adsorption chromatographic procedure was developed in order to fractionate synthetic fuels into various chemical-type classes for studying the relative concentrations and mutagenic activities of the various types. An SRC-II Heavy Distillate was fractionated into aliphatic hydrocarbons, polycyclic aromatic hydrocarbons, sulfur heterocycles, indoles and carbazoles, azaarenes, and amino polycyclic aromatic hydrocarbons. It was found that the amino-PAH fraction contained most of the mutagenic activity. A survey was made for compounds containing both nitrogen and sulfur heteroatoms in their structures. A number of these compounds were detected by GC using nitrogen- and sulfur-selective detection. (ERA citation 06:021501)

Low-Rank Coal Study : National Needs for Resource Development. Volume 2. Resource Characterization.
Nov 80, 279p
Contract AC18-79FC10066

Comprehensive data are presented on the quantity, quality, and distribution of low-rank coal (subbituminous and lignite) deposits in the United States. The major lignite-bearing areas are the Fort Union Region and the Gulf Lignite Region, with the predominant strippable reserves being in the states of North Dakota, Montana, and Texas. The largest subbituminous coal deposits are in the Powder River Region of Montana and Wyoming, The San Juan Basin of New Mexico, and in Northern Alaska. For each of the low-rank coal-bearing regions, descriptions are provided of the geology; strippable reserves; active and planned mines; classification of identified resources by depth, seam thickness, sulfur content, and ash content; overburden characteristics; aquifers; and coal properties and characteristics. Low-rank coals are distinguished from bituminous coals by unique chemical and physical properties that affect their behavior in extraction, utilization, or conversion processes. The most characteristic properties of the organic fraction of low-rank coals are the high inherent moisture and oxygen contents, and the correspondingly low heating value. Mineral matter (ash) contents and compositions of all coals are highly variable; however, low-rank coals tend to have a higher proportion of the alkali components CaO, MgO, and Na sub 2 O. About 90% of the reserve base of US low-rank coal has less than one percent sulfur. Water resources in the major low-rank coal-bearing regions tend to have highly seasonal availabilities. Some areas appear to have ample water resources to support major new coal projects; in other areas such as Texas, water supplies may be constraining factor on development. (ERA citation 06:021543)

Heavy-Liquid Beneficiation of Fine Coal. Second Quarterly Report Supplement, January 1-March 31, 1981.
D. V. Keller, Jr., and F. J. Simmons. 1981, 9p
Contract AC22-80PC30139

In our second quarterly report we experienced some unusual phenomena that were counter to the rheological trends of solid slurries experienced in the past. Upon further analysis it appeared that a slip phenomenon was occurring between the rotor being used in the measurement system and the coal-liquid slurries. In order to correct for the slip experienced, a profiled sensor was employed identical to the smooth sensor previously used with respect to length and diameter, but with vertical grooves approximately 1 mm wide by 1 mm deep evenly spaced around the rotor and running the full length of the rotor. Identical grooves were inside the walls of the cylinder. These grooves presented a surface that was more sensitive to the effects of the particles with respect to the overall slurry viscosity. The second phenomenon observed was the apparent migration of the particles away from the rotor as shear rate increased. This phenomenon can only be corrected by staying at a sufficiently low shear rate. The data obtained from a reevaluation of the solids volume percent, specific gravity and size distribution are presented graphically in figures 1 and 2. It is very evident when comparisons are made with the data presented in our second quarterly report that the profiled sensor system is more sensitive to the contribution of the solids to the overall slurry viscosity. Tests of the profiled sensor using Newtonian viscosity standards produced the same results as obtained with the smooth sensor. (ERA citation 06:023071)

Hydroliquefaction of Coal with Supported Catalysts: 1980 Status Review.
L. M. Polinski, G. J. Stiegel, and R. E. Tischer.
Jun 81, 124p

The objectives of the program have been to determine catalyst deactivation kinetic models and catalyst deactivation modes for supported Co-Mo and Ni-Mo catalysts used primarily in coal liquefaction via the H-COAL process. Emphasis has been on developing methods to increase catalyst usage by determining how to decrease catalyst replacement rates in the process and how to decrease catalyst poisoning. An important conclusion reached via model analysis and verified by experiment is that larger diameter (1/16 in.) catalysts resist poisoning deactivation much more than smaller (1/32 in.) catalysts over extended periods (60 to 110 hours) of time. If this trend can be verified, it gives a powerful tool for reducing catalyst

replacement rate in the H-COAL ebullated bed system by factors of 2 or more. A second conclusion is that poisoning of catalysts occurs by several possible mechanisms or modes. Indirect or direct evidence of all these modes can be presented, though the relative importance of each mechanism has not been established. The modes include (a) poisoning by coking - with gradual increase in C/H ratio (more refractory coke) with time, (b) poisoning by metallization (selective/non-selective adsorption of inorganics such as Ti and Fe on the catalyst), (c) sintering - increase in larger pores/decrease in surface area, and (d) parallel poisoning by irreversible nitrogen compound adsorption. A thermochemical cyclic process for producing hydrogen employs the reaction between ceric oxide and titanium dioxide to form cerium titanate and oxygen. The titanate is treated with an alkali metal hydroxide to give hydrogen, ceric oxide, an alkali metal titanate and water. Alkali metal titanate and water are boiled to give titanium dioxide which, along with ceric oxide, is recycled. (ERA citation 06:023242)

A series of fixed-bed coal gasification and pyrolysis tests have been performed in a laboratory-scale reactor of 6.6 cm inside diameter. Chemical analyses were conducted on the product gas, the aqueous condensate, the tar, and the solid residue from the tests. The effects of process variables, such as feed mode, catalytic treatment, pressure, mesh size, and coal type, upon byproduct and pollutant yields are described. The production of gaseous sulfur compounds, benzene and derivatives (BTX), phenolics (phenol, cresols, and xylenols), and tar have been measured, and the fate of trace elements such as arsenic, selenium, and lead has been determined. Byproduct production associated with the pyrolysis phase of gasification has been investigated with emphasis on the effects of particle size, residence time, and atmosphere. Experiments conducted with six U.S. coals ranging from lignite to anthracite are described. Continuous operation was found to result in greatly reduced tar and phenolic production. When the entire mass of coal was introduced at the beginning of the test, effluent stream compositions more closely approached those of larger scale, fixed-bed gasifiers. Initial work on this project was reported in PB-287720; three more recent reports were EPA-600/7-79-200 through EPA-600/7-79-202.

Alkali Vapor Transport in Coal Conversion and Combustion Systems.
Interim rept.,
J. W. Hastie, E. R. Plante, and D. W. Bonnell. May 81, 80p NBSIR-81-2279

Alkali metal-containing vapor species are ubiquitous in coal coversion and combustion systems. These species originate from coal mineral and atmospheric impurities (organic and inorganic) and from ceramic construction materials. Alternatively, they are present as additives, such as with potassium seeding for MHD or with bulk glass as a particle absorbing medium, or with dolomite in fluidized bed systems. Alkali vapor transport over representative slag, glass, and simple halide, hydroxide, and sulfate systems is discussed in relation to materials and process limitations in coal-supported energy systems. Problems associated with molecular-level vapor transport measurements are also considered.

The report gives results of a study to determine the extent of the present onsite use of waste fuel in industrial boilers and related process equipment, the nature and quantities of the materials so disposed of, and current regulations concerning such use. The study responds to a request for comment and advice on recently promulgated hazardous waste regulations that allow the onsite use of wastes as fuels with few restrictions. Based on contacts with federal, state, and local environmental protection officials, industry personnel, and the open literature, the study concludes that: a wide variety of materials have been burned as fuel in standard or appropriately modified combustion equipment; the practice can be expected to expand due to the economic pressures of hazardous waste disposal and rising fossil fuel costs; virtually no emission data on waste fuel combustion (except through incineration) is available; under conditions of inefficient combustion, significant particulate matter and high molecular weight (including polycyclic organic compounds) emission rates can be expected; and, within the scope of this study, no current regulations were found to be directed specifically at waste combustion. The study recommends increased industry contacts, representative site selection, and a field program in conjunction with a coordinated regulatory program.

The study was initiated with a review and analysis of Federal environmental regulations affecting gas supply technologies. An updated regulatory analysis appears in the final report. Next, the technological and environmental state of the art of each gas supply technology was analyzed with the help of a series of consultants recommended by GRI, each of whom is considered an expert in a given gas supply technology area. Based on regulatory requirements, technology status, and current environmental knowledge, the environmental issues associated with each technology area were identified. Environmental research being performed by government, industry and educational institutions was identified by computerized literature search and reviewed for applicability. Finally, recommended research activities for GRI funding were developed and a suitable prioritization methodology was devised.

The study seeks to enhance glycolic acid excretion by unicellular algae. The strains of algae selected to evaluate glycolic acid accumulation in culture medium were: Chlorella pyrenoidosa (UTEX 395), Chlamydomonas reinhardtii (UTEX 89), Scenedesmus obliquus (UTEX 393), and Ankistrodesmus braunii (UTEX 245). C. pyrenoidosa and C. reinhardtii, based on the amount of glycolic acid produced, were selected for further study. Initial experiments were conducted to measure the effect of different environmental growth conditions on the rate of glycolic accumulation in defined culture medium. The most pronounced effect on glycolic acid excretion was obtained by varying the concentration of carbon dioxide in air. At 1% CO2 in air, C. pyrenoidosa accumulated 5.2 ppm glycolic acid in culture medium. Neither the pH of the culture medium nor the incubation temperature affected glycolic acid accumulation by growing C. pyrenoidosa cultures.

A fuel distillate blend and a heavy distillate cut from SRC-II and a Paraho shale oil were chemically fractionated by Sephadex LH-20 chromatograhy, TLC and HPLC. Fractions were assayed for mutagenic activity by the Ames assay using Salmonella typhimurium TA98 with S9 and MFAO as metabolic activators. Fractions exhibiting mutagenic activity were characterized by GC-MS. The unfractionated Paraho shale oil was least mutagenic followed by the distillate blend and finally the heavy distillate cut. After Sephadex LH-20 chromatography, non-polar mutagens could not be detected in any of the synfuel samples; moderately polar mutagens made a small contribution to the samples total mutagenicity; most of the mutagenic activity appeared to be due to polar mutagens. After HPLC fractionation, the distillate blend exhibited non-polar mutagenic activity. The shale oil's mutagens ranged from moderately polar to polar. In contrast, the mutagens of the distillate blend and the heavy distillate cut were almost exclusively moderately polar. On the basis of the Ames assay with MFAO and the GC-MS analyses, primary aromatic amines appear to play a central role in the mutagenicity of the coal liquids. In contrast, amines do not appear to contribute as much to the activity of shale oil. (ERA citation 06:021516)

Contract AC04-76DP00789

This quarterly report summarizes the activities of Sandia National Laboratories' program on mineral matter effects in coal gasification. The objective of this program is to develop a fundamental understanding of the mechanism of the catalytic effects of mineral matter on coal gasification, and to use this knowledge as the impetus for future process improvements. We have identified reduced iron as the catalytic form of pyrite in the hydrogasification of a Pittsburgh Seam coal. We have observed catalytic activity of reduced iron that depends on precursor species in the following order Fe sub 2 O sub 3 > Fe sub 3 O sub 4 > FeS sub 2 > Fe. We have also found that, for a given iron compound, the catalytic activity is strongly dependent on particle size, with increasing activity for smaller average particle size. Using 5% by weight Fe sub 2 O sub 3 (approx. 5 mu), we measured a factor of 15 increase in the hydrogasification rate for a Pittsburgh Seam coal at 1000 exp 0 C and one atmosphere H sub 2 . Determination of the product gas composition indicates that the increase in gasification rate results primarily in methane production with reduced iron catalyst. (ERA citation 06:023038)

Why Solar Oil Shale Retorting Produces More Oil.
W. R. Aiman. 20 May 81, 5p
Contract W-7405-ENG-48

A solar oil shale retorting process may produce higher oil yield than conventional processing. High oil yield is obtained for three reasons: oil carbonization inside of the shale is reduced, oil cracking outside of the shale is reduced, and oil oxidation is essentially eliminated. Unique capabilities of focused solar energy produce these advantages. An increase in yield will reduce the cost of mining and shale transportation per barrel of oil produced. These cost reductions may justify the increased processing costs that will probably be associated with solar oil shale retorting. (ERA citation 06:021611)

A solar furnace study of zinc sulfate is proposed. In this study the advantages of the high temperatures and rapid heating rates provided by solar collectors for the decomposition of zinc sulfate will be investigated. The use of a rotary kiln designed to improve the efficiency in working with solids that have low absorbtivities, such as solid sulfates, is planned. The overall goal in this experiment is to establish the applicability of solar central receivers to thermochemical cycles that can use solid state sulfate decomposition as the high temperature step. The ZnSO sub 4 subcycle presents a number of operational advantages over the direct decomposition of H sub 2 SO sub 4 in the thermochemical process of hydrogen production from water. For instance, the cycle efficiency should increase due to reducing the heat requirements for evaporating water in the sulfuric acid concentration step. Also, a number of severe materials problems will be avoided for heat exchangers required to concentrate, boil, and decompose sulfuric acid. Furthermore, zinc sulfate lends itself well to coupling with solar central receivers, an alternative energy source which may introduce several additional advantages to sulfate-based thermochemical cycles. Much work is currently being carried out in the field of mathematical modelling of the physical and chemical processes taking place within combustion equipment to enable better combustion chamber design. One aspect of this is the numerical prediction of burning droplet trajectories in a gas flow field and in this paper a general three-dimensional particle/droplet trajectory algorithm is presented and applied to fuel sprays in gas turbine combustors. Droplet evaporation and initial heating up effects are included and trajectories are calculated within a three-dimensional computer predicted gas flow field. By injecting many droplets with initial conditions representing a particular fuel nozzle a complete fuel spray can be constructed, and this is presented graphically. The results show that in some cases the three-dimensional nature of the gas flow and the behaviour of large droplets may be expected to have a significant effect on combustor performance. (Author)

Combustor modelling methods involving stirred reactor networks require information on the volumes, inter-connections, mixedness and flowrates of the individual reactors. It is here proposed that the response of the system to a pseudo-random binary sequence (PRBS) stimulus can be used advantageously to fulfill this need. A survey is presented of the theory of the technique and method of interpretation of the results. The practicability of the method has been invesitgated experimentally using a water model of a gas turbine combustor; salt solution tracer was introduced into the primary flow in a PRBS and the conductivity at different points throughout the chamber was used to determine the impulse response and Z-transform. The results confirmed the anticipated sensitivity of the technique. Finally, the extension of the technique to the quantitative identification of non-linear elements is presented. (Author)

Computer Evaluation of the On-and-Off Design Performance of an Axial Air Turbine.
Master's thesis,
Robert Cirone. Mar 81, 268p

An existing code for calculating axial turbine performance using multiple stream surfaces was modified and made to run on the equivalent of an HP-1000 computer system. Calculations were made for the geometry of a 485 horsepower dual-discharge air-drive turbine for both on and off-design conditions. The results were compared with available data obtained at off-design speeds. Agreement of the flow rate and horsepower to within 5% was obtained. (Author)

Applications of Composite Gas Turbine Components. Phase I. Semi-Annual Technical Progress Report.
R. G. Kunkel. Mar 81, 27p
Contract AC01-80ET17005

Heavy-duty, air-cooled gas turbines utilize relatively large superalloy buckets and nozzle guide vanes. These large components, particularly buckets, must demonstrate a variety of properties. The airfoil vane requires excellent surface stability with high creep and low-cycle fatigue (LCF) strength. The dovetail requires excellent tensile strength and low-cycle fatigue (LCF) properties. Conventional buckets are fabricated as one single casting or forging in which compromises in these properties are inevitable, and the full capabilities of the superalloys used are rarely optimized along each individual line. A unique approach toward improved performance in key properties is to integrate the best material for each part of a hot section bucket or nozzle into a bonded composite component, or a hybrid component. A hybrid bucket is a superalloy part composed of a variety of alloys bonded into one integral part. Each segment is tailored to perform a specific function with greater reliability and performance than possible with contemporary monolithic parts. An example is a directionally-solidified (DS) airfoil vane bonded to a dovetail section of forged/PM superalloy. Several nickel base superalloy combinations which have been diffusion bonded using hot isostatic pressing (HIP). This technique enables large gas turbine buckets to be fabricated using materials with improved creep and low cycle fatigue life for the airfoil and greater high temperature tensile strength in the dovetail. The program will specifically investigate three directionally solidified airfoil alloys and two powdered metal dovetail alloys. This effort will include heat treat studies, physical metallurgy and high temperature tensile testing for all 5 alloys in their HIP bonded condition. (ERA citation 06:023417)

Final rept.,
E. Feder. Apr 81, 78p PWA-5706-16
Contract NAS3-22050

Aircraft engine structures were studied to identify the advanced structural technologies that would provide the most benefits to future aircraft operations. The following procedure was used. First, a series of studies identified engine systems with the greatest potential for improvements. Based on these studies six advanced generic structural concepts were selected and conceptually designed. Quantitative assessments were made of the benefits of each concept in terms of thrust specific fuel consumption, weight, cost, maintenance cost, fuel burned and direct operating cost plus interest. The probability of success of each concept was also determined. The concepts were ranked and the three most promising were selected for further study. This consisted of identifying and comprehensively outlining the advanced technologies required to develop these concepts for aircraft engine application. Analytic, fabrication and test technology developments are required. The technology programs outlined emphasize the need to provide basic, fundamental understanding of technology to obtain the benefit goals.

Contract NAS3-21468

The wind tunnel testing of a scale model of a tandem fan nacelle designed for a type (subsonic cruise) V/STOL aircraft configuration is discussed. The performance for the isolated front inlet and for the combined front and aft inlets is reported. Model variables include front and aft inlets with aft inlet variations of short and long aft inlet cowls, with a shaft simulator and diffuser vortex generators, cowl lip fillets, and nacelle strakes. Inlet pressure recovery, distortion, and inlet angle-to-attack separation limits were evaluated at tunnel velocity from 0 to 240 knots, angles-of-attack from -10 to +40 degrees and inlet flow rates corresponding to throat Mach number from 0.0 to 0.6. Combined nacelle pitch and yaw runs up to 30 deg. were also made.

Presented at the 17TH Joint Propulsion Conf., Colorado Springs, 27-29 Jul. 1981; Sponsored by Aiaa, Sae, and Asme.

Engine performance and mission studies were carried out for a single-spool Turbine Bypass Engine concept. Comparisons were made between the TBE, a conventional single-spool turbojet, and the Pratt & Whitney Variable Stream Control Engine. The airplane assumed for the study was a Mach 2.32 commercial supersonic transport. The nominal mission was a 4000-nautical miles total range with a 300-nautical miles subsonic cruise leg. The figure of merit was the minimum takeoff gross weight for the mission. Comparisons of the three engines were also made for the 4000-nautical miles total range with longer subsonic cruise legs.

As part of a continuing effort at the Lewis Research Center to improve performance, emissions, and reliability of turbine machinery, an investigation of fuel injection technique and effect of fuel type on small gas turbine combustors was undertaken. Performance and pollutant emission levels are documented over a range of simulated flight conditions for a reverse flow combustor configuration using simplex pressure-atomizing, spill-flow return, and splash cone airblast injectors. A parametric evaluation of the effect of increased combustor loading with each of the fuel injector types was obtained. Jet A and an experimental referee broad specification fuel were used to determine the effect of fuel type.

Proposed for Presentation at the 8TH Biennial Eng. Div. Conf., Hartford. Conn., 20-23 Sep. 1981; Sponsored by the American Society of Mechanical Engineers.

The effects of mistuning on flutter and forced response of a cascade in subsonic and

supersonic flow were investigated. The aerodynamic and structural coupling between the bending and torsional motions and the aerodynamic coupling between the blades were studied. It is shown that frequency mistuning always has a beneficial effect on flutter. For the cascade considered, the potential for raising flutter speed is greater in subsonic than in supersonic flow. Preliminary results for structural damping mistuning show that there are no additional benefits over adding damping mistuning may have either a beneficial or an adverse effect on forced response, depending on the engine order of the excitation and Mach number.

New Technique for the Direct Measurement of Core Noise from Aircraft Engines.
E. A. Krejsa. 1981, 25p NASA-TM-82634, E-859
Presented at the 17TH Joint Propulsion Conf., Colorado Springs, 27-29 Jul. 1981; Cosponsored by the Aiaa, Sae, and Asme.

The core noise levels from gas turbine aircraft engines were measured using a technique which requires that fluctuating pressures be measured in the far field and at two locations within the engine core. The cross spectra of these measurements are used to determine the levels of the far-field noise that propagated from the engine vore. The technique makes it possible to measure core noise levels even when other noise sources dominate. The technique was applied to signals measured from an Avco Lycoming YF102 turbofan engine. Core noise levels as a function of frequency and radiation angle were measured and are presented over a range of power settings.

a method is presented for the correction of the effect of finite rise time upon stress relaxation experiments. The basis for the correction relies on the Farris nonlinear homogeneous theory. In the limit of zero nonlinearity the correction is shown to agree with the correction by linear theory. In the limit of very strong nonlinearity the correction is achieved by redefining the zero of time to be at the end of the rise time. (Author)

The results of an investigation to select a satisfactory numerical method for calculating the propagation of steep fronted shock like waveforms in a solid rocket motor combusion chamber are presented. A number of different numerical schemes were evaluated by comparing the results obtained for three problems: the shock tube problem, the linear wave equation, and nonlinear wave propagation in a closed tube. The most promising method--a combination of the Lax-Wendroff, Hybrid and Artificial Compression techniques was incorporated into an existing non-linear instability program. The capability of the modified program to treat steep fronted wave instabilities in low smoke tactical motors was verified by solving a number of motor test cases with disturbance amplitudes as high as 80% of the mean pressure. Design analysis, detail design, fabrication, and experimental evaluation was performed on two self acting floating ring shaft seals for a rocket engine turbopump high pressure 24132500 n/sq m (3500 psig) hot gas 533 K 9500 F) high speed 3142 rad/sec (30000 rmp) turbine. The initial design used Rayleigh step hydrodynamic lift pads to assist in centering the seal ring with minimum rubbing contact. The final design used a convergent tapered bore to provide hydrostatic centering force. The Rayleigh step design was tested for 107 starts and 4.52 hours total. The leakage was satisfactory; however, the design was not acceptable due to excessive wear caused by inadequate centering force and failure of the sealing dam caused by erosion damage. The tapered bore design was tested for 370 starts and 15.93 hours total. Satisfactory performance for the required life of 7.5 hours per seal was successfully demonstrated.

The results of a test program to assess the potential of manned extravehicular activity (EVA) assembly of erectable space trusses are described. Seventeen tests were conducted in which six 'space-weight' columns were assembled into a regular tetrahedral cell by a team of two 'space'-suited test subjects. This cell represents the fundamental 'element' of a tetrahedral truss structure. The tests were conducted under simulated zero-gravity conditions. Both manual and simulated remote manipulator system modes were evaluated. Articulation limits of the pressure suit and zero gravity could be accommodated by work stations with foot restraints. The results of this study have confirmed that astronaut EVA assembly of large, erectable space structures is well within man's capabilities.

A wide variety of orbital cryogenic liquid storage and supply systems are defined in NASA and DOD long-range plans. These systems include small cooling applications, large chemical and electrical orbit transfer vehicles and resupply tankers. All have the common requirements of low-g fluid management to accomplish gas-free liquid expulsion and efficient thermal control to manage heat leak and tank pressure. A preliminary design study was performed to evaluate tanks ranging from 0.6 to 37.4 cu. 3 (22 to 1320 cu. ft). Liquids of interest were hydrogen, oxygen, methane, argon and helium. Conceptual designs were generated for each tank system and fluid dynamic, thermal and structural analyses were performed for Shuttle compatible operations. Design trades considered the paradox of conservative support structure and minimum thermal input. Orbital performance and weight data were developed, and a technology evaluation was completed. Flight derived longitudinal and lateral-directional stability and control derivatives were compared to wind-tunnel derived values. As a result of these comparisons, boundaries representing the uncertainties that could be expected from wind-tunnel predictions were established. These boundaries provide a useful guide for control system sensitivity studies prior to flight. The primary application for this data was the space shuttle, and as a result the configurations included in the study were those most applicable to the space shuttle. The configurations included conventional delta wing aircraft as well as the X-15 and lifting body vehicles.

Proposed Dynamic Phase Difference Method for the Detection of Tile Debonding from the Space Shuttle Orbiter.
A. J. Zuckerwar, and D. R. Sprinkle. Jun 81, 14p NASA-TM-83140

A noncontracting, semi-global, dynamic technique was developed for detecting loose tiles on the space shuttle orbiter. In laboratory tests on a single tile, the substrate was excited into lateral motion at a constant frequency and amplitude of 2g. The phase relationship between the motions of tile and substrate was examined by noncontacting probes in order to relate the dynamic properties of the tile SIP system to its fatigue history; by a visual technique using a stroboscope and split screen video monitor for practical application in the field. When the substrate is excited at an appropriate frequency (between 30 and 60 Hz), a good tile moves in phase and a loose tile out of phase with the substrate. The out of phase motion is readily observable in the form of a 'beat' between the tile and a reference marker on the substrate.

Software programs are designed to normalize the main problem in the theory of artificial satellites. At the onset, a canonical transformation of a new type, called the elimination of the parallax, reduces the system to a quasi-Keplerian one with varying angular momentum. As the first phase in a stepwise refinement, a separate radial intermediary is extracted from the simplified Hamiltonian; its normalization by a Poincare transformation executed is by a machine to the fourth order in closed form, that is to say, without developing the generator in powers of the eccentricity.

AD-A100 614/7 4733

Statistics of Nonlinearly Transformed Coherence Estimates.
AD-A101 098/2 4735

TRANSFORMERS
Partial Discharge Testing of Bulk Transformer Oil.
DE81023683 4704

TRANSIENT RESPONSE
Finite-Element Nonlinear Transient Response Computer Programs PLATE 1 and CIVM-PLATE 1 for the Analysis of Panels Subjected to Impulse or Impact Loads.
N81-26491/3 4803

TRANSLATIONS
Jovial (J73) to Ada Translator System.
AD-A100 881/2 4706

TRANSMISSION LINES
Electric and Magnetic Field Measurements.
PB81-218182 4704

TRANSMISSION LOSS
Very Low Frequency Transmission Loss in Shallow Water.

AD-A100 633/7 4794

Transmission Loss Prediction for the AN/TRC-97A Over a Tropospheric Scatter Path.
AD-A100 826/7 4776

TRANSMITTER RECEIVERS
Improved Hardware for Trolley Wire Phone Systems.
PB81-214363 4778

TRANSMITTERS
Worldwide OMEGA and Very Low Frequency (VLF) Transmitter Outages, January to December 1980.
AD-A100 835/8 4780

TRANSONIC FLOW
Viscous-Inviscid Interaction in Transonic Flow.
AD-A101 125/3 4622

TAIR: A Transonic Airfoil Analysis Computer Code.
N81-26074/7 4623

TRANSONIC WIND TUNNELS
Wind Tunnel Measurements of Total Force and Extremity Flail Potential Forces on a Crew Member in Close Proximity to a Cockpit.
AD-A100 917/4 4624

TRANSPARENCIES
An Improved System for Measuring Angular Deviation in a Transparency.
PAT-APPL-6-242 816 4771

TRANSPONDERS
Radar Beacon Transponder (RBX) Functional Description.
AD-A100 665/9 4781

Radar Beacon Transponder (RBX) Installation and Siting Criteria.
AD-A100 666/7 4781

TRANSPORT AIRCRAFT
Nasa's Role in Aeronautics: A Workshop. Volume 3: Transport Aircraft.
N81-26030/9 4623

TRANSPORT PROPERTIES
Analytical and Numerical Problems Associtated with Extending the Use of the Second order Even-parity Transport Equation.
AD-A100 801/0 4733

Structure and Ion Transport in Polymer-Salt Complexes.
AD-A101 157/6 4687

Ion-Pairing in Polyether Solid Electrolytes and Its Influence on Ion Transport.
AD-A101 161/8 4687

TRANSPORTATION ACCIDENTS
Hazards to Nuclear Power Plants from Nearby Accidents Involving Hazardous Material - Preliminary Assessment.
NUREG/CR-1748 4784

TRANSPORTATION NOISE
Environmental Issues in Transportation: Analysis, Noise, and Air Quality,
PB81-215261 4761

TRAVEL DEMAND
An Evaluation of Existing Travel Demand Estimation Procedures for Long Term Urban Transportation Planning.
PB81-214652 4747

TRAVELING WAVE TUBES
Analysis of a Broadband Cerenkov Amplifier.
AD-A100 628/7 4711

Theory of A Wideband Distribution Gyrotron Travelling Wave Amplifier.
AD-A100 757/4 4711

Linear 1 kW Multitone Troposcatter TWT.
AD-A100 888/7 4703

TRAVELING WAVES
Convergence of Periodic Wavetrains in the Limit of Large Wavelength.
AD-A100 609/7 4732

TREATMENT
Statistical Report: NIAAA Funded Treatment Programs, Calender Year 1979,
PB81-217531 4651

TROPICAL REGIONS

NTIS®

In this index, the name of the company, university, or government agency that performed the research or prepared the report is listed. Entries are arranged first by the organization's name, then alphanumerically by the performing organization report or series number. If no report or series number is included, the subarrangement is by NTIS order number.

NTIS ORDER/REPORT NUMBER INDEX

NTIS®

Entries in this index list the NTIS order number, the performing organization report number, and the sponsoring organization report number, each in its own alphanumeric position. Although reports may be ordered using only the performing organization report number or the sponsoring organization report number, please use the NTIS order number to order items available from NTIS to ensure faster service. It is best to check the full bibliographic citation in the Reports Announcements section before ordering. Entries are arranged alphanumerically.

Foreign NTIS Cooperating Organizations

NTIS is represented in many countries around the world by local organizations. These representatives ensure NTIS clients in those countries of fast and efficient service when transacting business with NTIS. They offer the convenience of accepting payment in local currencies and, any order-related problem can also be resolved by them. These representatives may also serve as an additional channel for non-U.S. information acquisitions.

NTIS clients in the countries listed below should direct all orders and inquiries to these representatives.
